

Figure 3

Multivariable MR estimates adjusted for BMI, education, and smoking initiation

* $P < 0.05$. Dashed line = $OR = 1$ (null hypothesis). CI = confidence interval.

MVMR estimates are exploratory sensitivity analyses; conditional F-statistics indicate adequate instrument strength.

Key Finding:

After adjusting for BMI, education, and smoking, MDD→Anxiety OR attenuated from 2.34 to 1.15, and Anxiety→MDD from 1.68 to 1.10, but both remained statistically significant — supporting partially independent causal pathways.
